

Fig. 14. Active nucleation site densities for the polished and rough surfaces as a function of Jakob number. Instantaneous active site density is shown with open symbols and dotted connectors, while cumulative active site density is shown with filled symbols and solid connectors.

The correlation of Benj, inverse relationship between parameter $R_a P/\sigma$ is greater. It is generally agreed that increase in number of nucleating cavities on a rough surface ($R_a P/\sigma > 100$) is well predicted. Agreement with the present data shows that the surface is as good as the H. The present experiments are underpredicted.

5.4. Terminal rise velocity

The terminal velocities of bubbles are compared with the theoretical values for small vapor bubbles rising in water. The balance of buoyancy and drag forces is used to predict the terminal velocity.
